

1. Abstract

Time management has become one of the main challenges for those who study or work in front of a screen. International research shows that most university students procrastinate frequently and that very few have a formal system to organize their activities (Garzón Umerenkova & Gil Flores, 2017; Svartdal et al., 2018). In Ecuador, this phenomenon is directly related to academic stress and poor performance, while in the city of Loja, there is limited local research on collaborative focus platforms and digital procrastination. This motivated the development of a web platform titled "Development of a web platform for online collaborative focus with random pairing to improve productivity in digital activities in the city of Loja."

The main goal was to develop a web platform for collaborative focus with random pairing that includes digital tools for time management. To do this, we reviewed scientific literature on procrastination and productivity, conducted a survey with people who do digital work in the city, and built the software using a hybrid approach that combines SCRUM with Extreme Programming practices in three phases: Pre-Game, Game, and Post-Game.

The solution developed was SINKA, a platform that connects two people randomly who want to focus at the same time. Both share a synchronized Pomodoro timer, can see each other on camera during work sessions, and can chat during breaks. The system rewards consistency with experience points, virtual coins, and daily streaks shown in a global ranking.
